GEOMETRIC PROGRAMMING SOLUTION OF SECOND DEGREE DIFFICULTY FOR CARBON EJECTION CONTROLLED RELIABLE SMART PRODUCTION SYSTEM

ANDREAS SE HO KUGELE¹, WAQAS AHMED² AND BISWAJIT SARKAR*¹,³

Abstract. Smart manufacturing systems should always aim to be fully sustainable while simultaneously being as reliable as possible which is difficult to reach. Furthermore, climate change especially by carbon emission in the industry is a significant topic and carbon emission should be controlled and reduced to save the environment. Contributing towards a greener environment in a positive manner is done by reducing the number of insufficient items that are produced in a smart production system which also can be reached with higher reliability in the system. Therefore, this study models a smart reliable production system with controlled carbon ejection. To solve the proposed smart production system in this study, a geometric programming approach with a degree of difficulty level two is used which results in optimum results that are quasi-closed. Furthermore, numerical experiments are conducted to validate the proposed model and prove that by using a higher degree geometric programming approach, an optimal solution is found. The numerical results do not only show optimal solutions but also that the smart production system with controlled carbon ejection is reliable.

1. Introduction

Smart production systems should always aim to reduce waste and be as environmentally friendly as possible. A positive contribution towards a greener environment in a smart production system may be inter alia gained by reducing the amount of waste that the manufacturing system is producing as well as controlling the carbon emission ejection. Furthermore, by making the smart production system reliable and sustainable, a great overall positive output can be gained. A smart production system is said to be reliable if there are no defective items. In addition, to call a smart production system (SPS) sustainable, the SPS must fulfill the pillars of sustainability. Hence, the smart production system must contribute towards a greener environment and bring economic as well as social benefits.

This study considers a smart reliable production system by using a reliability factor and also considering carbon emission ejection. To solve the study, a geometric programming approach is used. In geometric programming (GP), the degree of difficulty has great importance since it displays if there are no solutions, a unique solution, or many solutions. The degree of difficulty in the GP approach in the proposed reliable smart production system of this study equals two which indicates that there are many solutions. By executing numerical examples, it is found that it is possible to find a solution while operating with a higher degree of difficulty than one.

Furthermore, by using geometric programming, the optimum total cost can be found before finding the optimum of the four decision variables that are used which are production rate, reliability, production quantity, and setup cost under managed carbon ejection. In the following, the novelty of the proposed study is displayed:

- The proposed study develops a smart production system under consideration of controlled carbon emission to contribute to the prevention of excessive carbon emission of the manufacturing house which is needed for saving the environment as well as reducing health issues caused by intoxicated air.
- The proposed smart production system is developed in a reliable and sustainable manner. By maintaining a high degree of reliability and sustainability, the production of waste is reduced which contributes to a greener environment.
- Setting up a smart reliable production system is considered to be very expensive. Investments to reduce the expenditure for setup are implemented in the proposed model.
- The study is solved using a posynomial geometric programming method of second degree. Using the second degree geometric programming approach,
the optimum cost is found before finding optimum values of decision variables and the study proves that it is possible to find a unique solution utilizing the second degree geometric programming methodology.

This study is structured as follows: Section 2 covers the reviewed literature and Section 3 explains the complete model development of the smart reliable production system with managed carbon ejection. Section 4 deals with the geometric programming solution procedure in which before all else, the global minimum total cost expression is determined. Afterward, the optimum expressions of the four decision variables are determined. Section 5 validates the proposed model of a smart reliable production system with numerical examples and proves that a unique solution can be found while having a degree of difficulty equalling two. Additionally, a sensitivity analysis is conducted in Section 6. Section 7 covers the managerial insights and the last section concludes this study.

2. Literature review

Generally being able to control and reduce carbon emission ejection in smart production systems is inevitable to contribute to a greener environment. Production systems become more and more automated and show development towards smart production systems which is discussed by Kusiak [20]. Also, it is found that for changing a production system into a reliable production system, carbon emission ejection must be considered (Tiwari et al. [31]).

2.1. Smart production system

A smart and simultaneously sustainable production system that consists of numerous stages which also reduce waste and energy consumption is developed in a study by Sarkar and Sarkar [30]. In the case of a production enterprise, a methodology for developing it into a smart and sustainable production enterprise with sensing is developed by Chavarria-Barrientos et al. [7]. Furthermore, an increase in energy efficiency in a smart production system by controlling peripheral equipment is done by Bermeo-Ayerbe et al. [4]. Alavian et al. [2] developed a programmable production advisor that is able to find the current status of the system and improvements of a smart production system.

Also, a smart production system under a SCM is recently developed by Dey et al. [9] in which the lead time is controllable and safety stock, as well as planned backorder, have been considered. Furthermore, a setup cost reduction has been integrated. Relevant factors that decide the implementation of digital technologies as well as information of smart production is studied by Ghobakhloo [14]. The study of Sarkar et al. [28] covers a smart production system for a multi-type biofuel production. Their developed production system is sustainable and includes the implementation of renewable energies.
2.2. Reliability

Reliability can inter alia be defined by carbon emission and defectiveness of produced items. A way of reducing carbon emission is to implement smart energy systems. Important technologies and current developments of those smart systems and their impact on carbon emission are shown in a study by Zhu et al. [34]. Ahmed and Sarkar [1] have shown that if the cumulative expenditure under a carbon emission constraint of a sustainable manufacturing system is calculated, the cost is minimal. In a previous study of Wang et al. [32], it can be seen that carbon emission ejection influences the judgment of manufacturing and remanufacturing. Sarkar et al. [27] introduced a cleaner manufacturing system that consists of one stage in which a random quota of defectiveness and reworking are considered. Dey et al. [10] introduced an autonomation policy in a smart manner for a production system consisting of a single stage where hybrid production and remanufacturing is considered to reduce waste that is randomly produced within the system. Sarkar [26] developed a numerous-stage manufacturing system with numerous cycles and considers the management of insufficient products under a stochastic quota of defectiveness. A production system that is not reliable has been discussed in the study of Nahas [24]. Chen et al. [8] proposed an evaluation strategy that evaluates the reliability in a production system with numerous states. Furthermore, Wu and Cui [33] analyzed the reliability of systems that are periodically investigated.

A closed-loop supply chain model that simultaneously considers a conventional and green production under consideration of carbon emission from various sources and considering a stochastic demand is developed by Jauhari et al. [18]. Furthermore, Sarkar et al. [29] discussed inter alia carbon emission ejection and their effects in a SCM that is sustainable and an improvement of production quality in the case of items with defined lifetimes. A vague model with expenditure reliability of an incorporated manufacturing transportation supply chain is developed by Asim et al. [3] which is solved by numerous goal optimizations. Leung [21] found an optimum total cost of an economic production quantity model that considers reliability. In his study, he used a GP approach with a first degree of difficulty to find ideal decision variable values as well as the total expenditure.

2.3. Geometric Programming

A standard inventory model with various constraints is solved by El-Wakeel and Salman [12] with a geometric programming approach, yet reliability has not been considered. Liu [22] used a geometric programming approach with a degree of difficulty of zero to find the optimum profit as a global result. In a further step, Liu [23] used the concept of a signomial geometric programming approach in which the optimum profit is derived with the usage of interval coefficients and a quantity discount. Furthermore, a robust geometric programming approach is done in a study by Chassein and Goerigk [6].

Geometric programming can also be done in a fuzzy manner. Hence, Cao and
Wang [5] discussed the development of uncertain geometric programming. A power optimization of a digital circuit with process variations and time constraints by using fuzzy geometric programming is found by Ghavami et al. [13]. Dressler et al. [11] considered positive certificates build on accumulations of positive circuit polynomials and geometric programming which contains constraints for a polynomial optimization and combines those concepts. Jafarian et al. [17] proposed a programming approach consisting of two steps to solve a nonlinear problem with numerous objectives. The programming approach of the study combines geometric programming and fuzzy optimization techniques.

Kalaiarasi et al. [19] developed an economic quantity model with numerous items and solved their model with geometric programming in an uncertain manner using a variety of membership functions for the fuzzification process. Furthermore, Hayhoe et al. [15] used a posynomial geometric programming approach to solve an optimal control problem and find strategies for the best control method.

3. Mathematical model

This section of the study deals with the generation of the model. The mathematical model for this study is divided into a basic problem definition, followed up by notation that are used, assumptions that are made, and the full model development.

3.1. Problem definition

Production systems generally tend to produce a significant amount of defective items with an irregular quota of defectiveness and not be fully reliable even if it is a smart production system. Reliability has great importance not only when it comes to the quality of the products and the production system itself but also in terms of waste reduction and having a big positive impact on contributing towards a greener environment.

In a reliable production system, it is possible to reduce waste and have waste control while simultaneously being able to keep the quality of the products that are being produced. A production system that reduces waste instantly contributes to a greener environment. By additionally considering carbon emission ejection, a production system can be further significantly improved.

Therefore, this study deals with a smart reliable production system that considers carbon emission ejection. The goal of this study is to gain a significant improvement of a conventional production system by turning it into a smart production system and using a reliability factor under carbon emission and also obtaining a minimum total cost. To find an optimum production quantity, as well as optimum values for reliability, setup cost, an optimum production rate, and finally an optimum total cost, a geometric programming approach with a positive degree of difficulty is used in this study by which a quasi-closed form of an optimum solution can be found.

3.2. Notation

The notation that have been used in this study are the following:

<table>
<thead>
<tr>
<th>Decision variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\kappa$</td>
<td>expenditure for setup per setup ($/setup$)</td>
</tr>
<tr>
<td>$\eta$</td>
<td>quota of production (units/unit time)</td>
</tr>
<tr>
<td>$\delta$</td>
<td>manufacturing process reliability</td>
</tr>
<tr>
<td>$q$</td>
<td>production quantity (units/batch)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\zeta(\kappa, \delta)$</td>
<td>expenditure for depreciation and interest ($/year$)</td>
</tr>
<tr>
<td>$TC(\kappa, \eta, \delta, q)$</td>
<td>total expenditure of the smart production system ($/year$)</td>
</tr>
<tr>
<td>$c_D$</td>
<td>development cost function</td>
</tr>
</tbody>
</table>
The following assumptions are considered for the development of the model in this study.

(1) The considered reliable smart production system only produces one kind of item and each item is inspected. In case a defective item is found at the inspection, the insufficient item is being removed to keep the smart production system reliable.

(2) The reliable smart production system controls carbon emissions, which leads to a reduction of carbon emission ejection and contributes to saving the environment. Each cost that is considered in this study is also considered with managed carbon ejection.

(3) To lower the expenditure for setup, an investment function is considered, which is as follows: \( \Xi = \xi \kappa^2 \), where \( \xi \) is the scaling parameter. Furthermore, the time boundary is considered to be not existent (Guchhait et al. [16]).

(4) The model of this study considers a depreciation and interest cost in which the reliability is considered and is contrarily proportional to the setup cost. The depreciation and interest cost is formulated as follows: \( \zeta(\kappa, \delta) = a\kappa^{-b}\delta^c \), where the parameters a, b and c are the shape parameters which are constant real numbers that are greater than zero (Sadjadi et al. [25]).
3.4. Model development

3.4.1. Production cost

In a reliable smart production system, a production cost should be considered. For the production cost per cycle, the following equation is being used:

\[ p = (\alpha \eta + \frac{c_D}{\eta} + c_m) \frac{\tau}{\delta}, \]  

where \( \eta \) denotes the variable production quota. The parameter \( \alpha \) represents the tool cost function and \( c_D \) is the development cost. The parameter \( c_m \) represents the expenditure for raw materials.

3.4.2. Setup cost

Since this study deals with a production system, considering a setup cost is mandatory. The reliable smart production system is dependant on the reliability of the product since the reliability factor influences the acceptable quality of the product that can satisfy the demand. Therefore, the length of a cycle has to be \( \delta q / \tau \). Hence, the expenditure for setup per cycle is as follows:

\[ \omega = \frac{\kappa \tau}{\delta}, \]  

(2)

3.4.3. Investment cost

Since the setup for a reliable smart production system is very high, a reduction of the setup cost is considered in this study. Therefore, the following investment function is introduced to reduce the setup cost:

\[ \Xi = \xi \frac{\kappa^2}{2}, \]  

(3)

where \( \xi \) is the scaling parameter.

3.4.4. Inventory holding cost

The expenditure for holding inventory is also a mandatory cost that has to be considered in a reliable smart production system. Hence, the expenditure of holding inventory is as follows:

\[ H_c = \frac{\chi q \delta}{2}. \]  

(4)

3.4.5. Depreciation and interest cost

Since the decision variable \( \delta \) represents the reliability, the unreliability can be written as \( 1 - \delta \) and the depreciation and interest cost can be formulated as the following:

\[ \zeta(\kappa, \delta) = a \kappa^{-b} (1 - \delta)^{-c_1}. \]  

(5)
The reliability factor $\delta$ can take values between zero and one. It is impossible for a product to be perfectly reliable and in case the equation for unreliability is being used and if $\delta$ goes to 1, it means that Equation 5 goes to $\infty$. This would mean that the closed-form optimum solution for this model is not possible to be found. Hence, the following equation for the depreciation and interest cost is used for the model of the reliable smart production system:

$$\zeta(\kappa, \delta) = ak^{-b} \delta^c,$$

where $a, b$ and $c$ are the shape parameters and the following holds: $a, b, c > 0$.

3.4.6. Total cost

The total cost of the reliable smart production system under controlled carbon emission per production cycle can be found by adding all the previously mentioned costs:

- Production cost
- Setup cost
- Investment cost to reduce the setup cost
- Inventory holding cost
- Depreciation and interest cost

The mathematical formulation of the accumulated expenditure is the following:

$$TC(\kappa, q, \delta, \eta) = \tau \kappa q^{-1} \delta^{-1} + \alpha \eta \tau \delta^{-1} + \frac{c_P \tau}{\eta \delta} + c_m \tau \delta^{-1} + \frac{\chi q \delta}{2} + \tau ak^{-b} q^{-1} \delta^{c-1} + \xi \frac{\kappa^2}{2},$$

where $\eta, \kappa, q, \delta > 0$.

4. Geometric programming solution to the mathematical model

To solve the previously proposed model, a geometric programming approach is used. In geometric programming, an important factor is the degree of difficulty through which one can obtain information if the model has a unique solution, many solutions, or no solutions. The degree of difficulty in this study equals two, which implies that there are many solutions. The aim of this study is to find an optimum minimum cost under carbon emission of the proposed smart production system at a degree of difficulty of two. When it comes to geometric programming, two different categories are existent in which one is called posynomial, and the
other is called signomial. Both categories contain power functions but in a signomial problem, one or more coefficients are negative while in a posynomial problem all coefficients have to be positive. By using a geometric programming approach, the optimum minimum cost can be found before calculating the ideal values of the decision variables by finding the optimum values of the dual variables. The following equations are considered to find an optimum solution of this model through geometric programming:

\[
\begin{align*}
\mu_1 &= \tau \kappa q^{-1} \delta^{-1} \\
\mu_2 &= \alpha \eta \tau \delta^{-1} \\
\mu_3 &= \frac{c_D \tau}{\eta \delta} \\
\mu_4 &= c_m \tau \delta^{-1} \\
\mu_5 &= \frac{\chi q \delta}{2} \\
\mu_6 &= \tau a \kappa^{-b} q^{-1} \delta^{-1} \\
\mu_7 &= \xi \kappa^2 \\
\end{align*}
\]

The previously mentioned total cost equation can be written in the following form:

\[
TC(\kappa, q, \delta, \eta) = \mu_1 + \mu_2 + \mu_3 + \mu_4 + \mu_5 + \mu_6 + \mu_7 \\
\geq \begin{pmatrix} \mu_1 \\ \mu_2 \\ \mu_3 \\ \mu_4 \\ \mu_5 \\ \mu_6 \\ \mu_7 \end{pmatrix} \begin{pmatrix} \varphi_1 \\ \varphi_2 \\ \varphi_3 \\ \varphi_4 \\ \varphi_5 \\ \varphi_6 \\ \varphi_7 \end{pmatrix} \\
\equiv \begin{pmatrix} \varphi_1 \\ \varphi_2 \\ \varphi_3 \\ \varphi_4 \\ \varphi_5 \\ \varphi_6 \\ \varphi_7 \end{pmatrix} \begin{pmatrix} \varphi_1 \\ \varphi_2 \\ \varphi_3 \\ \varphi_4 \\ \varphi_5 \\ \varphi_6 \\ \varphi_7 \end{pmatrix}
\]

Furthermore, the sum of \(\varphi_1\) to \(\varphi_7\) must equal to 1 and \(\varphi_1\) to \(\varphi_7\) must be greater than 0.

Equation (15) consists of a primal function that is shown on the left side of the equation and a dual function that is displayed on the right-hand side of the function. The column vector \(\varphi\) consists of the normalized dual variables \(\varphi_1\) to \(\varphi_7\). By
using the values of \( \mu_1 \) to \( \mu_7 \), the following equation is found:

\[
\phi(\varphi, \kappa, q, \delta, \eta) = \left( \frac{\tau \kappa q^{-1} \delta^{-1}}{\varphi_1} \right)^{\varphi_1} \left( \frac{\alpha q \tau^{-1} \delta^{-1}}{\varphi_2} \right)^{\varphi_2} \left( \frac{c_D \tau \eta^{-1} \delta^{-1}}{\varphi_3} \right)^{\varphi_3} \left( \frac{c_m \tau \delta^{-1}}{\varphi_4} \right)^{\varphi_4} \\
\left( \frac{\chi q \delta}{2 \varphi_5} \right)^{\varphi_5} \left( \frac{\tau \kappa^{-1} q^{-1} \delta^{-1}}{\varphi_6} \right)^{\varphi_6} \left( \frac{\xi \kappa^2}{2 \varphi_7} \right)^{\varphi_7}
\]

\[
= \left( \frac{\tau}{\varphi_1} \right)^{\varphi_1} \left( \frac{\alpha T}{\varphi_2} \right)^{\varphi_2} \left( \frac{c_D T}{\varphi_3} \right)^{\varphi_3} \left( \frac{c_m T}{\varphi_4} \right)^{\varphi_4} \left( \frac{\chi}{2 \varphi_5} \right)^{\varphi_5} \\
\left( \frac{\tau a}{\varphi_6} \right)^{\varphi_6} \left( \frac{\xi}{2 \varphi_7} \right)^{\varphi_7}
\]

\[ \eta^{\varphi_2 - \varphi_3} \kappa^{\varphi_1 - b \varphi_6 + 2 \varphi_7} q^{-\varphi_1 + \varphi_5 - \varphi_6 \delta - \varphi_1 - \varphi_2 - \varphi_3 - \varphi_4 + \varphi_5 + \varphi_6 (c - 1)}, \quad (16) \]

in which \( \varphi \) is arbitrary, which means that the exponents of each decision variable equals to zero.

Hence, equation (16) can be written as follows:

\[
\phi(\varphi_1, \varphi_2, \varphi_3, \varphi_4, \varphi_5, \varphi_6, \varphi_7) = \left( \frac{\tau}{\varphi_1} \right)^{\varphi_1} \left( \frac{\alpha T}{\varphi_2} \right)^{\varphi_2} \left( \frac{c_D T}{\varphi_3} \right)^{\varphi_3} \left( \frac{c_m T}{\varphi_4} \right)^{\varphi_4} \left( \frac{\chi}{2 \varphi_5} \right)^{\varphi_5} \\
\left( \frac{\tau a}{\varphi_6} \right)^{\varphi_6} \left( \frac{\xi}{2 \varphi_7} \right)^{\varphi_7}
\]

\[ (17) \]

The model is accepted when the orthogonality and normality conditions hold. The orthogonality and normality conditions are as follows:

\[
\varphi_2 - \varphi_3 = 0 \quad (18) \\
\varphi_1 - b \varphi_6 + 2 \varphi_7 = 0 \quad (19) \\
-\varphi_1 + \varphi_5 - \varphi_6 = 0 \quad (20) \\
-\varphi_1 - \varphi_2 - \varphi_3 - \varphi_4 + \varphi_5 + \varphi_6 (c - 1) = 0 \quad (21) \\
\varphi_1 + \varphi_2 + \varphi_3 + \varphi_4 + \varphi_5 + \varphi_6 + \varphi_7 = 1. \quad (22)
\]

Furthermore, the degree of difficulty has to be specified to know if geometric programming can be used. The degree of difficulty (DoD) can be found as follows:

\[
\text{DoD} = \text{Number of terms} - \text{Number of decision variables} - 1 \quad (23)
\]

\[
= \begin{cases} 
\text{unique solution}, & \text{if degree of difficulty} = 0 \\
\text{many solutions}, & \text{if degree of difficulty} > 0 \\
\text{no solution}, & \text{if degree of difficulty} < 0
\end{cases}
\]
Hence, the degree of difficulty in this model is the following:

\[
\text{The degree of difficulty} = 7 - 4 - 1 = 2. \tag{24}
\]

The solutions of \(\varphi_1, \varphi_2, \varphi_3, \varphi_5\) and \(\varphi_6\) in terms of \(\varphi_4\) and \(\varphi_7\) are the following:

\[
\varphi_1 = b \left( \frac{\left( -1 - 3\varphi_7 \right)}{-2 - 2b - c} \right) - 2\varphi_7 \tag{25}
\]

\[
\varphi_2 = \left( 1 - \varphi_4 - \left( 1 - c \left( \frac{-1 - 3\varphi_7}{-2 - 2b - c} \right) - \varphi_7 \right) \right) - \left( 1 + b \right) \left( \frac{-1 - 3\varphi_7}{-2 - 2b - c} \right) + \varphi_7 \frac{1}{2} \tag{26}
\]

\[
\varphi_3 = \left( 1 - \varphi_4 - \left( 1 - c \left( \frac{-1 - 3\varphi_7}{-2 - 2b - c} \right) - \varphi_7 \right) \right) - \left( 1 + b \right) \left( \frac{-1 - 3\varphi_7}{-2 - 2b - c} \right) + \varphi_7 \frac{1}{2} \tag{27}
\]

\[
\varphi_5 = 1 - c \left( \frac{-1 - 3\varphi_7}{-2 - 2b - c} \right) - \varphi_7 \tag{28}
\]

\[
\varphi_6 = \frac{-1 - 3\varphi_7}{-2 - 2b - c} \tag{29}
\]

To maximize the dual function with optimal \(\varphi_4^*\) and \(\varphi_7^*\), a logarithm of the function (17) can be used. Hence, the following equation can be obtained:

\[
X(\varphi_4, \varphi_7) = \ln \phi(\varphi_4, \varphi_7)
\]

\[
= \varphi_1 \ln \left( \frac{\tau}{\varphi_1} \right) + \varphi_2 \ln \left( \frac{\alpha \tau}{\varphi_2} \right) + \varphi_3 \ln \left( \frac{\sigma \beta \tau}{\varphi_3} \right) + \varphi_4 \ln \left( \frac{\sigma m \tau}{\varphi_4} \right)
\]

\[
+ \varphi_5 \ln \left( \frac{\frac{\tau}{\varphi_5}}{\varphi_5} \right) + \varphi_6 \ln \left( \frac{\tau a}{\varphi_6} \right) + \varphi_7 \ln \left( \frac{\xi \frac{1}{2}}{\varphi_7} \right). \tag{30}
\]
From equation (17), one can get the following:

\[
TC(\kappa, q, \delta, \eta) \geq \phi^*(\varphi_1^*, \varphi_2^*, \varphi_3^*, \varphi_4^*, \varphi_5^*, \varphi_6^*, \varphi_7^*)
\]

\[
= \phi(\varphi_1^*, \varphi_2^*, \varphi_3^*, \varphi_4^*, \varphi_5^*, \varphi_6^*, \varphi_7^*)
\]

\[
= \left( \frac{\tau}{\varphi_1^*} \right)^{\varphi_1^*} \left( \frac{\alpha \tau}{\varphi_2^*} \right)^{\varphi_2^*} \left( \frac{c_{\text{D}} \tau}{\varphi_3^*} \right)^{\varphi_3^*} \left( \frac{c_{m\tau}}{\varphi_4^*} \right)^{\varphi_4^*} \left( \frac{\chi}{\varphi_5^*} \right)^{\varphi_5^*} \left( \frac{\tau a}{\varphi_6^*} \right)^{\varphi_6^*} \left( \frac{\xi}{\varphi_7^*} \right)^{\varphi_7^*}
\]

(31)

Taking the equation (31) into consideration, the following equation can be displayed:

\[
\text{Min } TC(\kappa, q, \delta, \eta) = \text{Max } \phi^*(\varphi_1^*, \varphi_2^*, \varphi_3^*, \varphi_4^*, \varphi_5^*, \varphi_6^*, \varphi_7^*)
\]

\[
= \varphi^*(\varphi_1^*, \varphi_2^*, \varphi_3^*, \varphi_4^*, \varphi_5^*, \varphi_6^*, \varphi_7^*)
\]

(32)

In the following, the global optimum values of the decision variables are found.

\[
\frac{\mu_1^*}{\varphi_1^*} = \frac{\mu_2^*}{\varphi_2^*} = \frac{\mu_3^*}{\varphi_3^*} = \frac{\mu_4^*}{\varphi_4^*} = \frac{\mu_5^*}{\varphi_5^*} = \frac{\mu_6^*}{\varphi_6^*} = \frac{\mu_7^*}{\varphi_7^*} = \theta.
\]

(33)

Using Equation 15, the following can be obtained:

\[
\theta^{\varphi_1^*+\varphi_2^*+\varphi_3^*+\varphi_4^*+\varphi_5^*+\varphi_6^*} = \theta = \phi^*.
\]

Hence, \( \mu_i^* = \varphi_i^* \phi^* \), \( i = 1, 2, 3, 4, 5, 6, 7 \).

From Equation 34, the following applies:

\[
\mu_7^* = \varphi_7^* \phi^*
\]

which implies \( \kappa^* = \sqrt{\frac{2\phi^* \varphi_7^*}{\xi}}. \)

(35)

The optimum expression for \( \delta \) is as follows:

\[
\mu_4^* = \varphi_4^* \phi^*
\]

and \( \delta^* = \frac{c_{m\tau}}{\phi^* \varphi_4^*}. \)

(36)

Furthermore, the optimum production rate is expressed as follows:

\[
\mu_2^* = \varphi_2^* \phi^*
\]

which implies \( \eta^* = \frac{\phi^* \varphi_2^* \delta^*}{\alpha \tau} = \frac{\phi^* \varphi_2^* \left( \frac{c_{m\tau}}{\varphi_4^*} \right)}{\alpha \tau}. \)

(37)
and optimum \( q \) is the following:

\[
\mu_1^* = \phi_1^* \phi^* \\
\text{which leads to } q^* = \frac{\tau \kappa^*}{\delta^* \phi^* \phi_1^*} = \frac{\tau \left( \sqrt{\phi_1^* \phi_2^*} \right)}{\phi_1^* \phi_2^*} \phi^* \phi_1^*
\]

(38)

5. Numerical Example

To approve the proposed model of this study, numerical examples have been conducted in this section. Geometric programming is the only methodology in which the optimum total cost can be obtained without obtaining optimum values for decision variables. According to geometric programming theory, each value of optimum \( \phi_1^* \) to \( \phi_7^* \) must be greater than zero and the sum of \( \phi_1^* \) to \( \phi_7^* \) equals to one. This study conducts numerical examples for two different scenarios to validate the model. The Appendix contains the Hessian matrices and determinant values for both scenarios of the dual function. \( H_{11} \) is in both cases negative and \( H_{22} \) is in both cases positive which indicates that the global maximum is found. Referring to Equation 32, the global maximum of the dual function is the global minimum of the total cost function.

Scenario 1

Table 2 displays the input data that is used to conduct the numerical experiment of Scenario 1. The optimum values for \( \phi_1^*, \phi_2^*, \phi_3^*, \phi_4^*, \phi_5^*, \phi_6^*, \phi_7^* \) of Scenario 1 are displayed in Table 3.

Furthermore, the optimum values of the four decision variables and the optimum cumulated expenditure of Scenario 1 are displayed in Table 4.
Scenario 1 considers that the manufacturer has a demand of 600 units and an inventory holding cost of 5\$ per unit. Furthermore, the scaling factor for the investment to reduce the expenditure of setup is taken as 2200 and the material cost is considered to be 0.005\$ per unit. Using the input data from Table 2, the optimum values of $\varphi_1^*$ to $\varphi_7^*$ can be obtained from which the optimum total expenditure is found. Afterwards, the optimum values of the decision variables are identified. The proposed reliable smart production system in Scenario 1 has a 97% reliability which is displayed by the parameter $\delta^*$. Figure 1 displays the graphical representation of optimization for Scenario 1 using the dual variables $\varphi_4$ and $\varphi_7$. The maximum of $\phi^*(\varphi_1^*, \varphi_2^*, \varphi_3^*, \varphi_4^*, \varphi_5^*, \varphi_6^*, \varphi_7^*)$ is the minimum of $TC(\kappa, q, \delta, \eta)$ (refer to equation 32).

**Scenario 2**

A second scenario of the proposed model is considered to further validate and enhance the effectiveness of the study. Scenario 2 considers a reduced holding cost per unit which is changed to 3\$ per unit while the considered demand is increased by 20 units. Furthermore, the development and material cost have been reduced. Additionally, the scaling parameter for the investment function is reduced on a large scale from 2200 to 800. Table 5 displays the considered input data and Table 6 shows the optimum values of $\varphi_1^*$ to $\varphi_7^*$ for Scenario 2 of the proposed model.

</tr>
</tbody>
</table>

NA is inserted for the case that it is "Not Applicable".

For the investigation of sensibility of the first scenario of the proposed model in this study, the influence of changes of the considered cost parameters are inspected. The notation "NA" implicates that changing the cost parameter in the associated manner, it is mathematically not possible in this particular model to find the total cost. In case of higher the tool cost or development cost above 25%, results cannot be given with the used input data and by using geometric programming since the variables \( \varphi_4 \) and \( \varphi_7 \) both come in terms of imaginary numbers. The same result occurs for lowering the unit holding cost to 25% or lower.

The sensitivity analysis shows that the material cost \( c_m \) does almost not influence the optimum total cost at all by changing its values. The most influential and significantly high changes of the total cost occur by changing the tool cost and development cost. Both costs influence the total cost in the same manner. In case of decreasing the tool cost or development cost by 25%, the total cost reduces by around 12.5% and reducing those costs by 50% results in a total cost reduction of around 32.5%. If the holding cost per unit is increased by 25% and 50%, the total expenditure increases by approximately 2% and 4%, respectively. The sensitivity analysis shows that adjusting the tool cost and development cost are the best choices for lowering the total cost due to their high sensitivity impact on the total cost. Figure 3 displays a graphical representation of the sensitivity analysis of Scenario 1. Table 9 displays the sensitivity analysis of Scenario 2 of the proposed model.

</tr>
</tbody>
</table>

NA is inserted for the case that it is "Not Applicable".
The sensitivity analysis for Scenario 2 shows that similar to Scenario 1, the development cost and tool cost behave in the same manner and have the biggest impact on the total expenditure. Increasing those costs by 25% and 50% leads to an increase in the total expenditure by around 9.4% and 17.7%, respectively. Decreasing the unit holding cost in Scenario 2 of the model by 25% reduces the total cost by almost 3% and decreasing it by 50% reduces the total cost by around 7%. Changing the material cost almost has no impact on the total expenditure. Figure 4 shows a graphical display of the sensitivity analysis for Scenario 2.

7. Managerial insights

This section discusses the industrial benefits for industry managers and are as follows:

- Implementing a reliable smart production system is necessary to protect the environment and reduce carbon emissions in the industrial sector as well as making the production system more sustainable. Additionally to the positive effects of a greener environment, a smart reliable production system allows the industrial manager to be more responsive to the market environment and enhances the manager’s ability to compete in it.
- Considering Figure 3 and Figure 4 of this study, the industrial manager must concentrate on the tool cost as well as development expenditure. The figures show that the two expenditures are highly sensible for reducing as well as increasing the total cost. On the contrary, the industrial manager does not need to focus much on the raw material cost due to its low sensibility and should keep an eye on the inventory holding cost.
- Since the expenditure for setup may be very high, the industrial manager should consider using the discrete investment used in this study to reduce the setup cost.
- The industrial manager should also consider using a geometric programming approach for evaluating changes. Using the geometric programming approach, which this study proves can be done with a second degree of difficulty, the industrial manager can find the total expenditure before finding the optimum values of decision variables. Hence, the industrial manager can find out in a faster manner if and how much beneficial it is to have changes in input parameters without knowing the optimum values of the decision variables yet.

8. Conclusions

The model of this study considers a smart production system with controlled carbon ejection that is sustainable. In the development of this study, an investment cost has been included to lower the setup cost of the reliable smart manufacturing system. Furthermore, a reliability factor $\delta$ has been used and is seen as a decision variable. The optimum production quantity, as well as setup cost, are found. To solve the proposed model of this study, a geometric programming approach is used. The advantage of using geometric programming as a methodology is that the global optimum total cost can be found before finding the ideal values of the decision variables. When it comes to geometric programming, the degree of difficulty displays if there are no solutions, a unique solution, or many solutions. Thus far in the literature, any model that has been solved with geometric programming either had a degree of difficulty of 0 (unique solution) or a degree of difficulty of 1 (many solutions). Not only is this proposed study developing a smart production system
with controlled carbon ejection, but also solves the model via geometric program-
ing that has a degree of difficulty of 2. By conducting numerical examples, the
proposed model is validated and a minimum total cost is found. Furthermore,
the numerical examples prove that an optimum solution can be found by using
a geometric programming approach with a degree of difficulty of 2. Hence, this
study proves that with a degree of difficulty of 2, geometric programming can be
used to solve the model.

The proposed model may be extended in various ways. One way to extend the
study may be to further develop the proposed manufacturing system that consists
of a singular stage to a numerous-stage manufacturing system or even numerous-
stage with numerous cycles (Sarkar [26]). Also, an extension may be done by
slightly changing the model and solving it with a higher degree of difficulty than 2
by inter alia using constraints such as a space constraint for storage. To make the
proposed smart and reliable production system even more sustainable and have a
greater impact on a greener environment, the study can be extended by consider-
ning renewable energies (Sarkar and Sarkar [30]). Furthermore, to make the study
closer to reality, fuzziness could be introduced (Ghavami et al. [13]). The proposed
model considers a smart production system with controlled carbon emission and
uses a posynomial geometric programming approach to solve it. Advancing the
smart and reliable production system by inter alia further introducing a holding
cost for not only perfect but also insufficient items and a reworking expenditure as
well as considering random defective rates during the manufacturing process (Dey
et al. [10]), the proposed study is not able to be solved by geometric programming
in a posynomial manner and a signomial geometric programming approach can be
used (Liu [23]).
